Antiepileptic drugs (AEDs) are widely used as long-term adjunctive therapy or as monotherapy in epilepsy and other indications and consist of a group of drugs that are highly susceptible to interactions. During the last years several new AEDs have been marketed. Initially, all new AEDs are licensed for add-on therapy for epilepsy patients.

and to younger patients, certain factors carry greater weight. Selection of the appropriate therapy should be guided by the recognition that older patients often have comorbidity and receive multiple medications.

Antiepileptic Drugs in the Elderly - Oxford Medicine

Abstract. Antiepileptic drugs (AEDs) are routinely prescribed for the management of a variety of neurologic and psychiatric conditions, including epilepsy and epilepsy syndromes. Physiologic changes due to aging, pregnancy, nutritional status, drug interactions, and diseases (ie, those involving liver and kidney function) can affect pharmacokinetics of AEDs.

The use of antiepileptic drugs (AEDs) is the primary modality for the mitigation of symptoms and disease management. AEDs are a diverse group of compounds with a history reaching back to the 1800s. From a historical perspective, potassium bromide was the first compound used therapeutically for recurrent seizures (4).

Background: Antiepileptic drugs (AEDs) are the mainstay of epilepsy treatment. Since 1989, 18 new AEDs have been licensed for clinical use and there are now 27 licensed AEDs in total for the treatment of patients with epilepsy. Furthermore, several AEDs are also used for the management of other medical conditions, for example, pain and bipolar disorder.
